

Kitchen Roots: Data Model (v7)

Physical SQLite schema with field data types and ordered Recipe steps.

Notes

Recipe_Ingredient, Recipe_Tag, and Recipe_Note are join tables. Each resolves a many-to-many relationship into two one-to-many relationships.

Recipe_Step is a child table, not a join table: one Recipe owns many ordered steps, and each step belongs to exactly one Recipe. step_number preserves cooking order.

A many-to-many cannot be stored with a foreign key on either side, because a column holds only one value per row. The join table is the only way to implement it.

Note.note_type distinguishes family story, region, heritage, technique, and other reusable note categories without adding new tables.

amount and unit live on Recipe_Ingredient because they describe how an Ingredient is used in one specific Recipe. For "5 bouillon cubes," amount is 5 and unit is cubes.

SQLite uses type affinity, so the storage classes here are INTEGER and TEXT. amount is TEXT so values such as 1/2, to taste, or 2-3 can be stored; prep_time is INTEGER minutes.

Recipe.user_id ties each Recipe to its owning User. Recipe.tier remains a dormant free/premium flag for a future paywall.
